Take Home Assignment 1

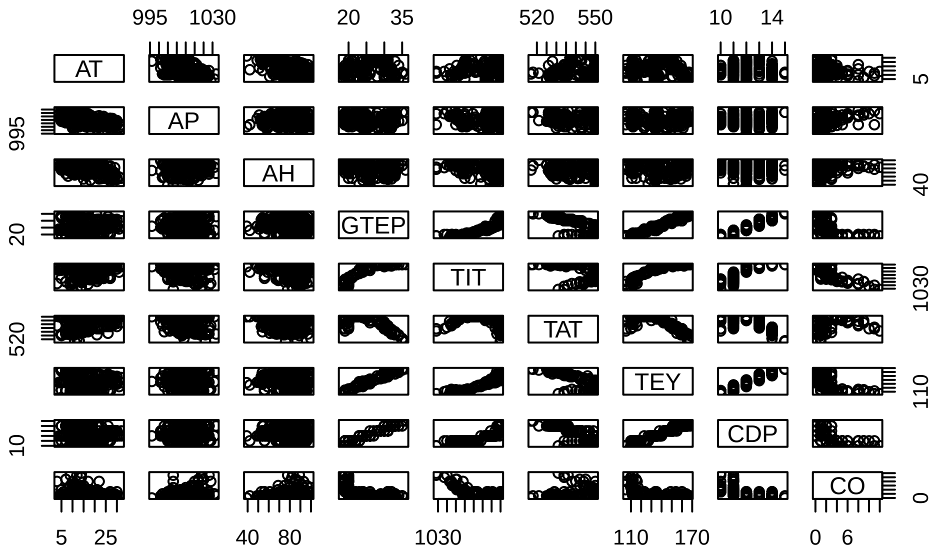
Jan Ryszkiewicz

Task 1

subtask 1

Let's perform basic inspection:

```r
load("Data ST523 813 E2025 Exam.rdata")
df <- Data
pairs(df)
```



```r
nrow(df)
```

```
[1] 300
```

```r
ncol(df)
```

```
[1] 9
```

```r
summary(df)
```

```
       AT               AP              AH              GTEP            TIT      
 Min.   : 3.00   Min.   : 996   Min.   : 39.00   Min.   :18.00   Min.   :1028

 Max.   :550.0   Max.   :168.0   Max.   :15.00   Max.   :12.0  
```

Then try fitting a default model:

```r
model = lm(CO ~ AT + AP + AH + GTEP + TIT + TAT + CDP + TEY, data = df)
```

subtask 2

Then show the parameters as well as the change in CO when Ambient Temperature (AT) increases by 1 degree C:

```r
coef(model)
```

```
  (Intercept)            AT            AP            AH          GTEP 
124.201440581  -0.021611280   0.009736961  -0.009621796  -0.370650220 
          TIT           TAT           CDP           TEY 
  0.029651998  -0.255240883  -0.463761682  -0.068439127 
```

```r
coef(model)["AT"]
```

```
         AT 
-0.02161128 
```

subtask 3

Perform F-Test:

```r
summary(model)
```

```

Call:
lm(formula = CO ~ AT + AP + AH + GTEP + TIT + TAT + CDP + TEY, 
    data = df)

Residuals:
    Min      1Q  Median      3Q     Max 
-2.8724 -0.5804 -0.0571  0.4270  4.3507 

Coefficients:
              Estimate Std. Error t value Pr(>|t|)    
(Intercept) 124.201441  17.933449   6.926 2.78e-11 ***
AT           -0.021611   0.028025  -0.771 0.441242    
AP            0.009737   0.012831   0.759 0.448558    
AH           -0.009622   0.005824  -1.652 0.099605 .  
GTEP         -0.370650   0.158512  -2.338 0.020048 *  
TIT           0.029652   0.058304   0.509 0.611437    
TAT          -0.255241   0.072992  -3.497 0.000544 ***
CDP          -0.463762   0.221422  -2.094 0.037083 *  
TEY          -0.068439   0.071399  -0.959 0.338581    
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 0.9744 on 291 degrees of freedom
Multiple R-squared:  0.7386,    Adjusted R-squared:  0.7314 
F-statistic: 102.8 on 8 and 291 DF,  p-value: < 2.2e-16
```

As we can see:

```
F-statistic: 102.8 on 8 and 291 DF,  p-value: < 2.2e-16
```

P-value is very low which indicates the rejection of H_0 - global null hypotesis at significance $\alpha = 0.05$

We have 291 residual degrees of freedom (n - p) and 8 model degrees of freedom (p - 1)

Value of the F-test statistic is 102.8

subtask 4

Let's start by fitting 2 submodels:

```
M_A = lm(CO ~ AT + AP + AH, data = df)
M_B = lm(CO ~ GTEP + TIT + TAT + CDP + TEY, data = df)
```

Now try comparing ambient only model to the default:

```
anova(M_A, model)
```

```
Analysis of Variance Table

Model 1: CO ~ AT + AP + AH
Model 2: CO ~ AT + AP + AH + GTEP + TIT + TAT + CDP + TEY
  Res.Df    RSS Df Sum of Sq     F    Pr(>F)
1    296 971.35
2    291 276.31  5    695.04 146.4 < 2.2e-16 ***
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

As we can see by the corresponding F-statistic (146.4) and p-value ($<$ 2.2e-16) The default model explains the data *much better*

What about the process only model?:

```
anova(M_B, model)
```

```
Analysis of Variance Table

Model 1: CO ~ GTEP + TIT + TAT + CDP + TEY
Model 2: CO ~ AT + AP + AH + GTEP + TIT + TAT + CDP + TEY
  Res.Df    RSS Df Sum of Sq      F Pr(>F)
1    294 281.35
2    291 276.31  3    5.0342 1.7673 0.1535
```

Here we can see, that rejection of the null hypotesis being that default model explains the data better is not possible, as the corresponding F statistic (~ 1.76) and p-value (0.15) suggest the redundancy of ambient variables in the fitting i. e. adding $AT + AP + AH$ predictors to Process Only fit does **not** significantly improve the model.

Therefore we conclude that we *can reduce* the default model to the Process Only one as it does not significantly worsen the model.

subtask 5

First I would like to try and find even better fit:

```
anova(M_B)
```

```
Analysis of Variance Table

Response: CO
           Df Sum Sq Mean Sq  F value    Pr(>F)
GTEP        1 341.46  341.46 356.8233 < 2.2e-16 ***
TIT         1 401.59  401.59 419.6583 < 2.2e-16 ***
TAT         1  24.64   24.64  25.7507 6.899e-07 ***
CDP         1   5.96    5.96   6.2230   0.01316 *
TEY         1   2.00    2.00   2.0886   0.14946
Residuals 294 281.35    0.96
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

By playing around with **anova**'s chain of hypotesis testing indicates the possibility fitting an alternative model, as including TEY as predictor appears unnecessary:

```
M_Alt = lm(CO ~ GTEP + TIT + TAT + CDP, data = df)
anova(M_Alt, M_B)
```

```
Analysis of Variance Table

Model 1: CO ~ GTEP + TIT + TAT + CDP
Model 2: CO ~ GTEP + TIT + TAT + CDP + TEY
  Res.Df    RSS Df Sum of Sq      F Pr(>F)
1    295 283.34
2    294 281.35  1    1.9987 2.0886 0.1495
```

Here, in the F test we can see that p value isnt lower that $\alpha = 0.05$ therefore reducing the number of variables again doesnt seem to worsen the model - we can use the alternative one from now on.

By inspecting adjusted R^2 between models we can see that the jump between our alternative model and the one proposed in the last subtask is not that significant.

```
R_Ambient = summary(M_A)$adj.r.squared
R_Alt = summary(M_Alt)$adj.r.squared
R_Process = summary(M_B)$adj.r.squared
R_default = summary(model)$adj.r.squared

R_Ambient
```

```
[1] 0.07171319
```

```
R_Alt
```

```
[1] 0.7283011
```

```
R_Process
```

```
[1] 0.7293
```

```
R_default
```

```
[1] 0.731403
```

The final inspection of variation let's choose Process Only model M_B:

```
explained_variation = summary(M_B)$r.squared
CO = df$CO
TSS = sum((CO - mean(CO))^2)
RSS = sum(residuals(M_B)^2)
absolute_reduction = TSS - RSS

explained_variation
```

```
[1] 0.7338268
```

```r
absolute_reduction
```

```
[1] 775.6549
```

It is worth performing similar inspection for the alternate model M_Alt:

```r
explained_variation = summary(M_Alt)$r.squared
RSS = sum(residuals(M_Alt)^2)
absolute_reduction = TSS - RSS

explained_variation
```

```
[1] 0.7319358
```

```r
absolute_reduction
```

```
[1] 773.6562
```

The absolute reduction in the residual sum of squares is only slightly higher for model M_B, at the cost of including one additional predictor. Depending on the available computational power, we can choose to either stay by M_B for marginally better performance or opt for the slightly lighter M_Alt, which performs almost equivalently.

Task 2

subtask 1

The model presented in task can also be written as:

$$X = \begin{bmatrix} 1 & 0 & 0 & 0 & X_1 \\ 1 & 0 & 0 & 0 & X_2 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 1 & 0 & 0 & X_{\scriptscriptstyle 2} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 0 & 1 & 0 & X_{\scriptscriptstyle 3} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 0 & 0 & 1 & X_{\scriptscriptstyle 4} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 0 & 0 & 0 & X_{45} \end{bmatrix}, \quad \beta = \begin{bmatrix} \mu \\ \alpha_2 \\ \alpha_3 \\ \alpha_4 \\ b \end{bmatrix}, \quad Y = \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_{45} \end{bmatrix}.$$

Where each column $2, 3, 4$ in X is filled with $0, 1$ depending on corresponding $\alpha_{i(j)}$ And column 1 corresponds to always present μ

Also α_i defined as:

$$\begin{aligned}
\alpha_2 &= \text{Temporary – Research/Academic (relative to Permanent)} \\
\alpha_3 &= \text{Temporary – Private Consultant (relative to Permanent)} \\
\alpha_4 &= \text{Freelance (relative to Permanent)}
\end{aligned}$$

We know that:

$$\begin{aligned}
\text{Cov}(\hat{\alpha}_2, \hat{\alpha}_3) &= 22{,}000{,}000 \\
\text{Cov}(\hat{\alpha}_2, \hat{\alpha}_4) &= 20{,}000{,}000 \\
\text{Cov}(\hat{\alpha}_3, \hat{\alpha}_4) &= 21{,}000{,}000
\end{aligned}$$

And:

$$\begin{aligned}
\widehat{\text{SE}}(\hat{\mu}) &= 20{,}000 \\
\widehat{\text{SE}}(\hat{\alpha}_2) &= 24{,}000 \\
\widehat{\text{SE}}(\hat{\alpha}_3) &= 23{,}000 \\
\widehat{\text{SE}}(\hat{\alpha}_4) &= 22{,}000
\end{aligned}$$

First we want to calculate the CL for $\alpha_2 - \alpha_3$ with confidence 90%

Which is:

$$\begin{aligned}
c &= [0, 1, -1, 0, 0], \\
\hat{\psi} &= c^T\hat{\beta} = \hat{\alpha}_2 - \hat{\alpha}_3, \\
\widehat{\text{SE}}(\hat{\psi}) &= \sqrt{cVar(\hat{\beta})c^T}, \\
&= \sqrt{Var(\hat{\alpha}_2 - \hat{\alpha}_3)} \\
&= \sqrt{Var(\hat{\alpha}_2) + Var(\hat{\alpha}_3) - 2Cov(\hat{\alpha}_2, \hat{\alpha}_3)}, \\
\text{CI}_{90\%} &= \hat{\psi} \pm t_{45-5,\, 1-0.10/2} \cdot \widehat{\text{SE}}(\hat{\psi})
\end{aligned}$$

That then by substitution becomes:

$$
\begin{aligned}
\hat{\psi} &= -40{,}000 - (-10{,}000) \\
&= -30{,}000 \\
\hat{\text{SE}}(\hat{\psi}) &= \sqrt{(24{,}000)^2 + (23{,}000)^2 - 2 \cdot 22{,}000{,}000} \\
&\approx 32{,}573 \\
t_{40,\,(1-0.10)/2} &\approx 1.68385 \\
\text{CI}_{90\%} &= \hat{\psi} \pm t_{45-5,\,1-0.10/2} \cdot \hat{\text{SE}}(\hat{\psi}) \\
\text{CI}_{90\%} &= -30{,}000 \pm 1.68385 \cdot 32{,}573 \\
&= -30{,}000 \pm 54848
\end{aligned}
$$

Therefore the Confidence interval is:

$$\text{CI}_{90\%} = [-84{,}848\ ,\ 24{,}848]$$

That concludes the first subtask of Task 2.

subtask 2

Next we want to look for statistical evidence for: $\alpha_2 \leq \alpha_3$

Therefore we perform One Sided hypotesis Test on:

$$
\begin{aligned}
H_0 &= \alpha_2 - \alpha_3 > 0 \\
H_a &= \alpha_2 - \alpha_3 \leq 0
\end{aligned}
$$

H_0 - temporary researchers are earning **more** than temporary private consultants

H_a - the opposite

We are using the same $\hat{\psi}$ from previous subtask:

$$
\begin{aligned}
\hat{\psi} &= \hat{\alpha}_2 - \hat{\alpha}_3 \\
T &= \frac{(\hat{\alpha}_2 - \hat{\alpha}_3) - 0}{\hat{\text{SE}}(\hat{\psi})} \\
&= \frac{-30{,}000}{32{,}573} \\
&\approx -0.921
\end{aligned}
$$

Then:

```r
qt(0.05, df = 40)
```

```
[1] -1.683851
```

$$-0.921 > -1.683851$$
$$T > t_{40,\,0.05}$$

We cannot reject H_0

Therefore there is not enough statistical evidence that temporary researchers are earning less than temporary private consultants.

Task 3

We have $x_i \in [-2, 2]$ for $i = 1, \dots, n$. The X and β matrces are as follows:

$$X = \begin{bmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_n \end{bmatrix}, \quad \beta = \begin{bmatrix} \beta_0 \\ \beta_1 \end{bmatrix}.$$

Therefore, the variance of $\hat{\beta}$ is

$$\mathrm{Var}(\hat{\beta}) = \sigma^2 (X^\top X)^{-1} = \sigma^2 \begin{bmatrix} n & \sum_i x_i \\ \sum_i x_i & \sum_i x_i^2 \end{bmatrix}^{-1}.$$

Following the inverse this becomes

$$\mathrm{Var}(\hat{\beta}) = \frac{\sigma^2}{n \sum_i x_i^2 - (\sum_i x_i)^2} \begin{bmatrix} \sum_i x_i^2 & -\sum_i x_i \\ -\sum_i x_i & n \end{bmatrix}.$$

And then, variance of the slope estimate $(\hat{\beta}_1)$ is:

$$\mathrm{Var}(\hat{\beta}_1) = \frac{\sigma^2 n}{n \sum_i x_i^2 - (\sum_i x_i)^2}$$

Which further reduces to:

$$\mathrm{Var}(\hat{\beta}_1) = \frac{\sigma^2}{\sum_i x_i^2 - \frac{1}{n}(\sum_i x_i)^2} = \frac{\sigma^2}{\sum_i x_i^2 - \frac{2}{n}(\sum_i x_i)^2 + \frac{1}{n}(\sum_i x_i)^2} =$$

$$= \frac{\sigma^2}{\sum_i x_i^2 - 2\sum_i x_i \cdot \bar{x} + n\bar{x}^2} = \frac{\sigma^2}{\sum_i (x_i - \bar{x})^2}$$

We want to minimize the $\text{Var}(\hat{\beta}_1)$. Which can be done by maximizing $\sum_i (x_i - \bar{x})^2$ as σ^2 is constant. This can be achieved by spreading $x_1, \dots, x_n$ as much as possible that will ideally set $\bar{x} = \frac{1}{n}\sum_i (x_i) = 0$

We know that:

$$x_i \in [-2, 2], \quad \forall i = 1, \dots, n$$

Then we can choose:

- $x_1, \dots, x_{n/2} = -2$
- $x_{n/2+1}, \dots, x_n = 2$

By that we minimize $\text{Var}(\hat{\beta}_1)$ now equal to:

$$\text{Var}(\hat{\beta}_1) = \frac{\sigma^2}{\sum_i (x_i - \bar{x})^2} = \frac{\sigma^2}{\sum_i (\pm 2 - 0)^2} = \frac{\sigma^2}{4n}$$

And we achive maximum possible precission

Q.E.D.

Task 4

Only for Master's
